This publication shows the number of households and average household size for Florida and each of its counties for 1970, 1980 and 1988. Households are defined as housing units occupied by permanent residents. They should not be confused with total housing units, which include vacant and seasonally occupied units as well as units occupied by permanent residents. According to the United States Bureau of the Census, a person is classified as a permanent resident of "...his usual place of residence, which is generally construed to mean the place where he lives and sleeps most of the time. This place is not necessarily the same as his legal residence, voting residence or domicile." The numbers shown in this bulletin refer only to the number of households and average household size of permanent Florida residents.

The data for 1970 and 1980 published in this bulletin were taken from actual census counts conducted by the United States Bureau of the Census. Data for 1988 were taken from estimates produced by the University of Florida Bureau of Economic and Business Research. Estimates of households were based on electric customer and building permit data (primarily the former). Estimates of average household size were based on each area's average household size in 1980, the national decline in average household size since 1980 and the local change in housing mix since 1980. A more detailed description of the methodology used to estimate households and average household size can be found in "Some New Techniques for Applying the Housing Unit Method of Local Population Estimation," *Demography*, Volume 17, Number 3, August 1980, pp. 323-339.

Number of households

There were 4,966,487 households in Florida on April 1, 1988, an increase of 1,222,233 (or 32.6 percent) since 1980. Dade County had by far the most households of any county in 1988, with 705,772. Other top counties were Broward (517,938), Pinellas (382,356), Palm Beach (348,239), Hillsborough (320,299), Duval (258,121) and Orange (237,392). The counties with the

smallest numbers of households were Lafayette (1,646), Liberty (1,734), Gilchrist (2,493), Union (2,662) and Glades (2,925).

Palm Beach had the largest increase in households between 1980 and 1988, growing by 113,900. Other large increases occurred in Broward (100,421), Dade (95,942), Hillsborough (82,356), Orange (66,638) and Pinellas (62,829). In terms of percentage growth rates, the most rapid increases in the number of households were found in Flagler (103.6 percent), Hernando (100.0 percent) and Osceola (98.7 percent). No county in Florida had a net loss in households between 1980 and 1988, but increases were less than 500 in Calhoun, Franklin, Gilchrist, Hamilton, Lafayette and Liberty counties.

Average household size

Average household size in Florida fell from 2.90 in 1970 to 2.55 in 1980, a decline of 12.1 percent. This percentage decline was almost identical to that found for the United States as a whole, where average household size fell from 3.14 in 1970 to 2.76 in 1980. These declines were caused by falling birth rates, increasing divorce rates and the growing tendency for single persons to live alone. In Florida an additional factor was the large number of retirees moving into the state; retirees typically live in one- or two-person households.

The trend toward smaller average household size has continued since 1980, but at a slower pace. Nationally, average household size fell to 2.64 in 1988, a decline of 4.3 percent since 1980. We estimate that average household size in Florida fell to 2.45 in 1988, a decline of 3.9 percent since 1980. The declines in average household size have been smaller in the 1980s than the 1970s because birth rates have increased a bit since 1980, divorce rates have leveled off and the number of young adults establishing their own households is not growing nearly as rapidly during the 1980s as it was during the 1970s.

Average household size in 1988 was largest in Gadsden and Baker counties, with 3.10 and 3.07, respectively. It was smallest in Pinellas (2.16), Charlotte (2.18) and Sarasota (2.19). In general, average household size tends to be higher for black than white households, for rural than urban households and for households headed by young and middle-aged persons. Although there is not a perfect correlation, the counties in Florida with the largest average household sizes tend to be rural and have a relatively high proportion of black households, whereas counties with the smallest average household sizes tend to be urban and have a relatively large proportion of older persons.

People are fascinated by the future. Palm readers, astrologers and crystal ball gazers down through the centuries have found eager buyers for their predictions. Modern-day researchers and forecasters, using computers and large-scale models, continue to find willing audiences. There is particularly great interest in population projections, and for good reason: many types of public and private planning--for schools, hospitals, stores, houses, service stations, roads and countless other projects--require some information on future population trends. Yet the future is essentially unknowable. No matter how scientific and sophisticated our projection techniques, we cannot perfectly predict future population trends. In spite of years of developing high-quality data, statistical techniques and computer programs, we still cannot "see" into the future.

We are not completely lost, of course. We can observe population trends that have occurred in the past. We can collect data and build models based on historical trends and relationships. We can then make projections from these models showing what would happen if past trends continued or varied in some particular way. Since the future is intimately tied to the past, these projections will often provide reasonably accurate forecasts of future population change. If constructed and interpreted properly, population projections--although certainly not perfect predictions of the future--can be extremely useful tools for planning and policy analysis.

The projections published in this bulletin are for the permanent resident population of Florida; they do not include tourists or part-time seasonal residents. Since the future cannot be predicted with absolute certainty, we have produced three sets of projections: low, medium and high. We believe the medium projection is generally more likely to provide an accurate forecast of future population than either the low or high projections. The low and high projections, however, provide an indication of the range in which the future populations might lie. While these projections provide useful benchmarks for planning and policy analysis, they should not be interpreted as the only possible scenarios for future population change. level should also be considered when using the projections for planning purposes (particularly for small counties).

State projections

State-level projections were made using a cohort-component methodology in which births, deaths and migration were projected separately for each age-sex cohort in the population. The starting point was the April 1, 1980 population of Florida as enumerated in the decennial census. Survival rates were applied to each age-sex cohort to project future mortality. These rates were based on Florida Life Tables for 1980, prepared by the Public Health Statistics Section of the Florida Department of Health and Rehabilitative Services. The survival rates were adjusted upward in 1990, 2000 and 2010 to account for projected increases in life expectancy (U.S. Census Bureau, *Current Population Reports*, Series P-25, No. 952, May 1984).

Migration rates were based on 1980 census data regarding migration behavior between 1975 and 1980. Inmigration rates were calculated by dividing 1975-1980 migration into Florida by the 1975 population of the United States (minus Florida) for each age-sex cohort. Outmigration rates were calculated by dividing 1975-1980 migration out of Florida by the 1975 Florida population for each age-sex cohort. Projections of inmigration were then made by applying inmigration rates to the population of the United States (minus Florida), and projections of outmigration were made by applying outmigration rates to the Florida population. The projections of the United States population were taken from *Current Population Reports*, Series P-25, No. 952, May 1984.

Projections were made in five-year intervals, with each projection serving as the base for the following projection. Projected inmigration for each five-year interval was added to the survived Florida population at the end of the interval, and projected outmigration was subtracted, giving a projection of the population age five and older. Births and net migration of children less than age five were projected by applying age-specific birth rates (adjusted for child mortality) to the projected female population. These birth rates were based on Florida birth data between 1980 and 1985, and imply a total fertility rate of 1.9 births per woman. The 1985 projection was adjusted to be consistent with the 1985 total population estimate, and the 1990 and 1995 projections were adjusted to be consistent with the 1990 and 1995 projections produced by the State of Florida's economic forecasting model.

Three different migration assumptions were used, providing three sets of projections. The low series applied a weight of 0.9 to the inmigration rates for each age-sex cohort. This series implies net inmigration (i.e. the excess of inmigrants over outmigrants) of 150,000 to 200,000 per year, about the same as during the low-growth years of the 1970s and 1980s. The high series applied a weight of 1.4 to the inmigration rates, yielding net migration numbers of 330,000 to 370,000 per year, about the same as during the high-growth years of the 1970s and 1980s. The medium series applied weights that differed by age group and over time. For persons less than age 65, the weights were 1.3 from 1980 to 1990, 1.27 from 1990 to 1995, 1.21 from 1995 to 2000 and 1.15 thereafter. For persons age 65 and older, the weights were 0.7 from 1980 to 1990 and 1.0 thereafter. Lower weights were used for older persons because Medicare data indicate that the elderly have accounted for a smaller proportion of net migration since 1980 than they did from 1975 to 1980. The middle series implies net migration of 210,000 to 270,000 per year, about the same as the annual average during the 1970s but somewhat below the annual average of the 1980s. We believe the medium series is the most likely to produce accurate forecasts of the Florida population.

County projections

While the cohort-component technique is a good way to make projections at the state level, it is not necessarily the best way to make projections at the county level. Many counties in Florida are so small that the number of persons in each age-sex category is inadequate for reliable cohort-component projections. Furthermore, county growth patterns are so volatile that a single technique based on the 1975-1980 time period may provide misleading results. We believe more useful projections can be made if a number of different techniques and historical time periods are used.

For counties we made nine projections using four different techniques and three different historical time periods. The starting point for each projection was the 1988 population estimate published by the Bureau of Economic and Business Research. Three projections were made using linear extrapolation. These were based on population growth during three different time periods: 1983-1988, 1978-1988 and 1973-1988. One projection was made by extrapolating the exponential growth rate that occurred between 1983 and 1988. Three projections were made using a share-of-growth technique in which it was assumed that each county's share of the state's future population growth would be the same as it was during the base periods of 1983-1988, 1978-1988 and 1973-1988. Two projections were made using a shift-share technique in which it was assumed that each county's share of state population would change annually by the same linear amount as the average annual change during the base periods of 1983-1988 and 1978-1988.

These techniques provided nine different sets of projections for each county. For 1990 the medium projection was based on an average of the four projections using 1983-1988 as a base period. For 1995 the medium projection was based on an average of all nine projections. For 2000 we used all nine projections but excluded the highest and lowest projections (thereby excluding techniques that may tend to "explode" upward or downward when carried too far into the future) and took an average of the seven remaining projections. For 2005, the medium projection excluded the two highest and two lowest projections and used an average of the five remaining projections. For 2010, the medium projection excluded the three highest and three lowest projections and used an average of the three remaining projections. Our research has shown that taking the average of a number of different projections reduces the chances of making large errors and leads to more reliable projections. For the years 2015 to 2020 we held each county's share of state population at the same level as it was in 2010. We believe that the continued extrapolation of past trends this far into the future is likely to be counterproductive. Some counties will grow more rapidly than the state as a whole, while others will grow more slowly. Unfortunately, there is no way to know in advance which counties will fall into which of these two categories. Consequently, we take a middle-of-the-road approach and hold county population shares constant.

In a number of counties we made special adjustments to the population before applying the techniques described above. This was done to account for such special populations as university students, foreign immigrants, military personnel and prison inmates. Adjustments were made for counties in which these special populations account for a large proportion of total population or where the special populations have moved counter to trends for the rest of the population. In the present set of projections adjustments were made for Alachua, Baker, Bradford, Brevard, Calhoun, Dade, Duval, Escambia, Gadsden, Hamilton, Hendry, Holmes, Jackson, Lafayette, Leon, Martin, Monroe, Okaloosa, Santa Rosa and Union counties.

The techniques described above were used to make the medium set of population projections. This is the set we believe is generally most likely to provide an accurate forecast of future population. In all cases medium county projections were controlled to add to the state medium projection. We have also made a low and high set of projections to provide an indication of the potential variation around the medium projection. The low and high projections were based on an analysis of the errors observed when the projection techniques were applied to a large data base encompassing almost 3,000 counties in the United States. Although the analysis is still preliminary, we believe there is roughly a two-thirds probability that future populations will fall between the low and high projections.

Note: For the medium series, the sum of the county projections equals the state projection for each year (except for slight differences due to rounding). For the high and low series, however, the sum of the county projections does not equal the state projections. This occurs because potential variation around the medium projection is much greater for counties (especially small and/or rapidly growing counties) than for the state as a whole.

Population Estimates and Projections by Age, Sex and Race for Florida and Its Counties, 1988-2000

by
Stanley K. Smith
Population Program Director

and

Ravi Bayya
Associate in Research

Bureau of Economic and Business Research
College of Business Administration
University of Florida

This report shows population estimates and projections by age, sex and race for Florida and each of its sixty-seven counties. The estimates are for April 1, 1988 and the projections are for April 1 of 1990, 1995 and 2000. These estimates and projections were made using a cohort-component methodology in which births, deaths and migration are projected separately for each age-sex-race cohort in the population. The numbers shown in this report have been controlled to be consistent with the estimates of total population published in *Florida Estimates of Population: April 1, 1988* (Bureau of Economic and Business Research, University of Florida, February 1989) and the medium series of projections of total population published in "Projections of Florida Population by County, 1988-2020," *Population Studies*, Bulletin Number 88 (Bureau of Economic and Business Research, University of Florida, March 1989).

The starting point for these estimates and projections was the April 1, 1980 population as enumerated in the decennial census. One major adjustment was made to the 1980 census data, however. This adjustment did not affect the total population count or the age and sex distribution of the population, but it had a substantial impact on the race distribution (especially for whites and persons of races other than white or black). This adjustment was made by the U.S. Bureau of the Census and involved the transfer of a number of Spanish-origin persons from the "Other Races" category to the "White" or "Black" categories. The great majority were reassigned as "White." A full description of the reasons and methodology for making this adjustment can be found in *Current Population Reports*, Series P-23, Number 139 (U.S. Bureau of the Census, 1985). As a consequence of this adjustment, the 1980 data by race shown in this report are different from those shown in earlier reports.

The projections were made in five-year intervals, with each projection serving as the base for the following projection. Projected births and in-migrants were added to the initial population, and projected deaths and outmigrants were subtracted, yielding a projection of the population five years later. Projections were made for the white and nonwhite population and the black population was estimated as a proportion of the nonwhite population. The following section provides a detailed description of the data and techniques used to make these projections.

Methodology

Mortality. Future deaths were accounted for by applying age-sex-race-specific survival rates to each age-sex-race cohort in the population. These rates were taken from the Florida Life Tables for 1980 prepared by

the Public Health Statistics Section of the Florida Department of Health and Rehabilitative Services. The survival rates were adjusted upward to account for projected increases in life expectancy. These adjustments were based on projected increases in life expectancy for the U.S. population as a whole (U.S. Bureau of the Census, *Current Population Reports*, Series P-25, No. 952, May 1984). The adjustments imply that survival rates in Florida will change at the same rate as survival rates in the United States for each age-sex-race cohort.

The application of five-year survival rates indicates the number of persons from the initial population expected to be alive after five years. State-level survival rates were used in each county because county-level rates are not available.

Migration. Migration is the major determinant of population growth in most counties in Florida. The migration rates used in these projections were based on county migration patterns between 1975 and 1980, as reported in the 1980 Census of Population. In-migration rates by age, sex and race were calculated by dividing migration into the county for each cohort by the 1975 population of the United States (excluding that county) in the corresponding cohort. Out-migration rates by age, sex and race were calculated by dividing migration out of the county for each cohort by the 1975 county population in the corresponding cohort. These migration rates indicate the relative probabilities of moving into or out of a county during a five-year interval.

The in-migration rates were adjusted to account for the higher rates of net migration into Florida since 1980 than occurred between 1975 and 1980. These adjustments were made by applying the following weights to the 1975-1980 in-migration rates:

Time period	<Age 65	Age 65+
1980-1985	1.300	0.7
1985-1990	1.275	0.8
1990-1995	1.250	0.9
1995-2000	1.225	1.0

The application of these weights provides population projections that are consistent with the 1985 population estimate and the 1990 econometric forecast for the state population. Different weights were applied to the population above and below age 65 because Medicare data show that the elderly have accounted for a smaller proportion of net in-migration since 1980 than between 1975 and 1980.

Projections of in-migration by age, sex and race were then made by applying the adjusted in-migration rates to the initial United States population and projections of out-migration were made by applying the out-migration rates to the initial county population. (Projections of in-migration were based on Census Bureau projections of the U.S. population, published in *Current Population Reports*, Series P-25, Number 952, May 1984.) These migration flows were further adjusted in several counties to account for large institutional populations. These adjustments were most important in Alachua and Leon counties, homes to the major state universities.

Fertility. Projected in-migration for each five-year interval was added to the survived county population at the end of that interval and projected out-migration was subtracted, giving a projection of the population age 5 and older. Births and net migration of children less than age 5 were projected by applying age-specific fertility rates (adjusted for child mortality) to the projected female population. These age-race-specific fertility rates were constructed for each county, based on birth data for 1985. Rates varied among counties from 1.04 to 2.81 for whites and from 1.34 to 4.73 for nonwhites. At the state level, these rates imply a total fertility rate of approximately 1.75 births per woman for whites and 2.67 births per woman for nonwhites. The population age 0-4 was divided between males and females using proportions of 0.51 and 0.49, respectively.

Discussion

Using the methodology just described, population projections by age, sex and race were made for April 1, 1985, 1990, 1995 and 2000. For 1985 only, two additional adjustments were made. The first affected the population age 0-4. Rather than using age-specific fertility rates, the estimate of this age group was based on the actual number of births in each county between 1980 and 1984. This calculation was made by forming a ratio of the 1980 population age 0-4 to the number of births between 1975 and 1979 for each county, and applying this ratio to the number of births between 1980 and 1984. We believe this technique provides a more accurate estimate of this age group than does the application of age-specific fertility rates.

The second adjustment for 1985 affected the population age 65 and older. Rather than using survival and migration rates to estimate this age group, Medicare data for 1980 and 1985 were used. For each county, a ratio was formed of the 1980 census population age 65 and older to the number of Medicare enrollees age 65 and older in 1980. This ratio was then applied to the number of Medicare enrollees age 65 and older in 1985, thereby providing an estimate of the total population age 65 and older for each county. We believe this approach provides a more accurate estimate of the elderly population than the application of survival and migration rates because the number of Medicare enrollees age 65 and older is very highly correlated with the population age 65 and older.

Two adjustments, then, were made to the population projections by age, sex and race for 1985. Both were based on symptomatic indicators of specific age groups in the population. Since these adjustments did not affect the estimates of total population for 1985, the effects of the adjustments were spread proportionally across all the five-year age groups between ages 5 and 64. The 1988 estimates by age, sex and race printed in this report were then made by interpolating between the 1985 estimates and the 1990 projections, controlling the results to add to the 1988 county estimates of total population (Bureau of Economic and Business Research, *Florida Estimates of Population: April 1, 1988*, February 1989.)

Estimates and projections by age and sex were made separately for the white and nonwhite populations of each county, using age-sex-race-specific survival, migration and fertility rates. These estimates and projections were summed and controlled to independent estimates and projections of the total population, as mentioned earlier. Estimates and projections of the black population were made by applying the 1980 ratio of blacks to nonwhites to the estimates and projections of the nonwhite population, for each age-sex cohort.

In this publication we show the age-sex distribution of the total population, the white population and the black population. Estimates and projections of the nonwhite population can be obtained by subtracting estimates and projections of the white population from estimates and projections of total population.

Conclusion

We believe the estimates and projections published in this report provide useful tools for policy planning and analysis. They are based on widely accepted techniques and the best data available. They should not be interpreted as perfect predictions of population change, however. Although they are based on reasonable assumptions, those assumptions will virtually always be erroneous to one degree or another. It is therefore imperative to consider alternative scenarios and other sources of information, especially for planning and analysis in small counties. These estimates and projections provide useful benchmarks for evaluating population change, but their tenuous nature must always be clearly recognized.

Note: This report provides estimates and projections only for the condensed age groups of 0-14, 15-24, 25-44, 45-64, 65+ and 18+. Complete estimates and projections by sex and race for five-year age groups are also available. Please contact the Bureau of Economic and Business Research for further information.
